Key Difference – Keloid vs Hypertrophic Scar

A scar that grows beyond the boundaries of the original wound is called a keloid scar whereas a scar that is raised above the skin level but grows within the boundaries of the original wound is known as a hypertrophic scar. As their definitions state, keloid scar grows out of the boundaries of the original wound but a hypertrophic scar grows within the boundaries of the original wound. This is the key difference between keloid scar and hypertrophic scar.

What is a Keloid Scar?

When the epithelium is damaged either due to tissue injury or due to the loss of integrity of the epithelium cells, the repair mechanisms are spontaneously activated. If the damage is minimal, the repairing happens through tissue regeneration. But in case of severe injury or repeated exposure to an injurious agent, the damaged tissues are inflamed. Some of the cytokines such as IL13 and TGF beta released by the inflamed cells stimulate the recruitment of fibroblasts, which later differentiate into myofibroblasts. The end result is the formation of a fibrous tissue mass. This process is known as fibrosis.
Keloid scars are due to the excessive formation of these scar tissues. When the scar extends beyond the boundaries of the original wound and does not regress, it is called a keloid scar.

**What is a Hypertrophic Scar?**

Hypertrophic scars are also a result of the excessive formation of collagen fibers during wound healing. Although these scars are raised above the skin level, they do not grow beyond the boundaries of the original wound.

**Treatment of Keloid and Hypertrophic Scars**

- Surgical excision
- Cryotherapy
- Compression therapy
- Radiation therapy
- Occlusive Dressings
Intralesional corticosteroid injections

**What is the Similarity Between Keloid and Hypertrophic Scar?**

- Both types of scars are due to the excessive production of collagen fibers during wound healing.

**Summary – Keloid vs Hypertrophic Scar**

A scar that grows beyond the boundaries of the original wound is called a keloid scar and a scar that is raised above the skin level but grows within the boundaries of the original wound is known as a hypertrophic scar. Unlike hypertrophic scars that grow within the limits of the original wound, a keloid scar grows beyond the boundaries of the original wound. This is the main difference between keloid scar and hypertrophic scar.
